

The Complete Wealth Dashboard Guide

From a single stock's signal to your whole financial future
Covering both the Holding-History analysis panel and the Wealth Center

What this is. Your dashboard now has two halves, and this guide teaches both from zero — no finance background needed. **Part A (the per-stock engine)** tells you whether *one* stock is a buy, sell, or hold and why. **Part B (the Wealth Center)** zooms out to your *whole* portfolio: what to do today, what your money truly earned, how risky your mix is, where your wealth has been, and — using simulation — where it could go. Every technical term is defined the moment it appears.

The golden rule. These tools turn real price, volume, and financial data into disciplined, transparent, honest opinions. They are decision-support, not fortune-telling. Their power is consistency: they show their work, grade their own confidence, and state plainly when they'd be wrong.

Map of the dashboard

Part A — Holding History tab → 'Institutional Sentiment & Analysis': one card per stock (recommendation, trust, conviction, fundamentals, trade plan, factors, signals). **Part B — Wealth Center tab:** Action Center, True Returns, Portfolio Risk, Allocation, Wealth Trajectory, Wealth Forecast, and the Financial-Independence Goal tracker.

Part A — Reading one stock's card

Every stock you own gets a card driven by a **multi-factor engine**: it scores seven independent factors, weights them, and blends them into one **Composite Score** (–100 to +100) that sets the recommendation and colour.

The seven factors

Factor	Wt*	The question it answers
Trend & MACD	22%	Is price rising or falling, and is that strengthening?
Momentum (RSI)	16%	Has it moved too far, too fast — due to bounce or pull back?
Institutional Flow	16%	Are big buyers accumulating (volume on the right days)?
Price Structure	13%	Near a floor (cheap) or a ceiling (pricey)?
Relative Strength	10%	Beating or lagging the market (EGX30)?
Fundamentals	16%	Is the company cheap, profitable, financially healthy?
Risk Profile	10%	How wild are the swings? (a penalty)

*Weights adapt: in a strong trend (high ADX) Trend counts more and Momentum less; missing data (e.g. no financials) drops that factor and re-weights the rest. Nothing is ever fabricated.

In plain English: Seven expert judges score a contestant; some votes count more, and a judge with no data that round abstains. The Composite is their weighted average.

Card items, top to bottom

What you see	What it means
Recommendation	BUY / ACCUMULATE / HOLD / SELL — the headline call from the Composite.
Trust chip	HIGH/MEDIUM/LOW — how reliable THIS analysis is (data quality + agreement), not whether the stock is good.
Conviction	0–99% — how strong and unanimous the opinion is.
PERF / Max DD / Vol	Recent return / worst peak-to-trough fall / how jumpy the price is (annualized).
Fundamentals	Real P/E, ROE, D/E, Dividend + a valuation verdict. Dashes mean 'not reported' — never a guess.
Context strip	ADX (trend strength), % vs Index, daily+weekly agreement, and a historical backtest hit-rate.
Trade Plan	Entry zone, stop-loss, risk:reward, and Bear/Base/Bull targets.
Position size	Shares to buy so you risk only ~2% of capital, plus the max EGP loss.
68% range	A statistical 3-month price band from volatility (honest uncertainty, no drift).
Factor bars	The 'show your work' — each factor green-right (positive) or red-left (negative).
Signals / Invalidation	Plain bullets, and the exact price that would prove the idea wrong.

In plain English: RSI is a stretched rubber band (snaps back past 30/70); ADX says how hard it's being pulled; support/resistance are the room's floor and ceiling; a stop-loss is your seatbelt.

Trust note on the AI narrative: the written paragraph is generated from the technical numbers and reflects your LAST 'Update Analytics' run — it can lag the live figures. Always trust the live factor bars, fundamentals, and trade plan over the prose.

Part B — The Wealth Center

Where Part A judges one stock, the Wealth Center manages the **whole portfolio and your financial future**. It has seven sections; we take them in order.

B.1 Action Center

A single, **urgency-ranked to-do list** that fuses each holding's engine verdict with its stop-loss, target, and how big the position is. Instead of reading eight cards, you get one prioritized list of what to actually do today.

Action	What it means
CRITICAL — Exit	Price hit the stop-loss; the idea failed — protect capital.
HIGH — Reduce / Take profit	Engine turned SELL, or price reached the target, or the position is over-concentrated.
MEDIUM — Add	A strong BUY setup with a defined entry zone.
LOW — Accumulate	Mildly bullish — build gradually on dips.

In plain English: Analysis you don't act on doesn't build wealth. The Action Center is the bridge from 'interesting' to 'done.' If it's empty, everything is on-plan — hold.

B.2 True Returns

Four numbers that answer “what did my money *actually* earn?” — far more honest than a simple profit figure.

Money-Weighted Return (XIRR). Your true *annualized* return, accounting for *when* each deposit was made. This is the number to compare against a bank deposit or any other investment.

XIRR

the single annual rate that makes all your dated cash-ins and cash-outs balance to today's value

Total Return on Capital. Simple gain versus all the money you put in (not annualized).

Real Return. Your annualized return *after inflation* — what your **purchasing power** actually did. Crucial in Egypt: a +20% year during 25% inflation is a real *loss*. The inflation figure is an editable assumption you control.

Real Return (Fisher)

$$\text{real} = (1 + \text{annual return}) / (1 + \text{inflation}) - 1$$

USD-Adjusted Return. Your EGP performance re-expressed in dollars, capturing currency devaluation over your actual holding period.

Reading	What it means
XIRR > inflation	You are genuinely growing wealth.
Real Return > 0	You beat inflation — purchasing power rose.
Real Return < 0	Nominal profit, but you lost purchasing power.

In plain English: Nominal return is the scoreboard; real return is the scoreboard after the referee (inflation) takes his cut. Only the second one feeds your family.

B.3 Portfolio Risk

Per-stock risk rolled up to the **whole book**.

Volatility (annualized): how much the whole portfolio swings. **Beta:** sensitivity to the market — 1.0 moves with EGX30, >1 amplifies it, <1 dampens it. **Sharpe Ratio:** return per unit of risk — above 1.0 is good, meaning you're well paid for the bumps. **Max Drawdown:** the worst peak-to-trough fall the book has suffered.

Sharpe Ratio

$$\text{Sharpe} = (\text{portfolio return} - \text{risk-free rate}) / \text{portfolio volatility}$$

HHI concentration. The Herfindahl-Hirschman Index (0–1) measures how lopsided your holdings are. Below 0.25 = healthily spread; above 0.25 = one or two names dominate, so a single bad day can hurt disproportionately. A banner flags it if so.

Reading	What it means
Sharpe ≥ 1	Strong risk-adjusted return.
Beta > 1.2	More volatile than the market — bigger ups and downs.
HHI > 0.25	Concentrated — consider trimming the top position.

B.4 Allocation

Two donut charts — your equity split **by position** and **by sector** — so hidden concentration is obvious at a glance. The legend lists each holding's share of the book.

In plain English: Five umbrella shops on one street aren't diversified — one sunny week hurts them all. The sector donut reveals exactly those overlaps.

B.5 Wealth Trajectory (your past)

Your net worth **reconstructed day-by-day** from your real transactions and historical prices. The **green area** is total net worth; the **grey dashed line** is the capital you contributed; **blue dots** mark deposits. The gap between green and grey is your **market gains** — money the market made for you, separate from money you added.

In plain English: It separates 'money I saved' from 'money my investments earned.' Watching the green pull away from the grey is watching compounding work.

B.6 Wealth Forecast (your future)

This is a **Monte-Carlo simulation**: the computer plays out **600 different possible futures** for your portfolio, each a random but realistic path based on your book's *actual* volatility. From those it draws a fan of outcomes.

Monte Carlo simply means 'run the dice many times and look at the spread.' Because markets are uncertain, one prediction is false precision; a *range* of outcomes is honest.

Element	What it means
Median (50%) line	The central, most-likely path.
Optimistic (90%)	Only ~10% of futures did better than this.

Pessimistic (10%)	~10% of futures did worse — your realistic downside.
Shaded band	The 10–90% range: where wealth most likely lands.

You control three **editable assumptions**: expected annual return, monthly contribution, and horizon. The volatility is taken from your real portfolio. Watch how adding even a small monthly amount lifts the whole fan — that is the power of regular investing made visible.

In plain English: A weather forecast doesn't say 'it will be 23.0°' — it gives a range and a confidence. The fan chart does the same for your wealth. Markets can still fall below the 10% line.

B.7 Financial Independence Goal

Set a **target net worth** and the simulation answers the two questions that matter most: **how likely** are you to reach it, and **roughly when**?

The **circular gauge** shows your probability of hitting the target within the horizon. The **verdict** states it in words (e.g. “At 15%/yr you are 92% likely to reach EGP 1,000,000 — expected around January 2037”).

The **blue S-curve** shows the cumulative chance of having reached the goal by each future date — it starts near 0% and climbs as time gives compounding room to work.

Probability	What it means
Probability $\geq$ 75%	On track — your plan is realistic.
45–75%	Plausible but not assured — small tweaks help a lot.
< 45%	Unlikely as set — raise contributions, extend the horizon, or adjust the target.

Every figure here is **deterministic**: the same inputs always produce the exact same probability and date, so the number you act on is stable and reproducible — not random noise.

In plain English: This turns a vague hope ('I want a million') into a measured plan ('92% odds by 2037') — and shows precisely which lever (save more, wait longer, take more/less risk) moves the odds.

Putting both halves together

A day in the dashboard. You open **Wealth Center**. The **Action Center** says POUL/ORWE/MPCI are LOW-priority 'Accumulate on dips' — nothing urgent. **True Returns:** XIRR +62%, but Real Return +30% after 25% inflation and only +5% in USD — you're winning, yet currency matters. **Risk:** Sharpe 0.94, well-diversified (HHI 0.13). **Trajectory** shows green pulling nicely above your contributions. **Forecast:** 5-year median ~EGP 400k. **Goal:** 92% chance of EGP 1,000,000 by ~2037. You then open one holding's **card in Part A** to decide exactly where to add. Macro plan + micro decision, in two tabs.

In plain English: Part B tells you WHAT to do and whether you're on track to your life goal; Part A tells you exactly HOW and WHERE to execute it.

Glossary — every term in one place

Term	Meaning
RSI	Relative Strength Index (0–100). <30 oversold, >70 overbought. Momentum gauge.
MACD	Confirms whether up/down momentum is strengthening.
ADX	Trend STRENGTH (not direction). ≥ 25 = strong, reliable trend.
SMA / EMA	Simple / Exponential Moving Average — the smoothed average price.
ATR	Average True Range — typical daily price travel; the ruler for stops and targets.
Bollinger Bands	Volatility envelope around price; a 'squeeze' warns of a breakout.
OBV	On-Balance Volume — tracks buying vs selling pressure (institutional flow).
Support / Resistance	Price floor where buyers appear / ceiling where sellers appear.
Volatility	How much price swings (stdev of returns, annualized). Higher = riskier.
Max Drawdown	Worst peak-to-trough fall. The maximum pain endured.
Beta	Sensitivity to the market. 1 moves with the index; >1 amplifies.
Sharpe Ratio	Return per unit of risk. >1 is good.
Relative Strength	Your return minus the market's. Leadership vs lagging.
P/E	Price-to-Earnings — years of profit you pay for. Lower can be cheaper.
ROE	Return on Equity — profit per pound of shareholder capital.
D/E	Debt-to-Equity — leverage. <0.5 conservative, >1.5 risky.
Dividend Yield	Annual cash payout as % of price.
HHI	Concentration index (0–1). >0.25 = lopsided portfolio.
Correlation	–1..+1. How closely two holdings move together.
Composite Score	–100..+100 weighted blend of all factors; sets the recommendation.
Conviction	How strong/unanimous the opinion is (0–99%).
Trust / Data Confidence	How reliable THIS analysis is, given data quality and agreement.
XIRR	Money-weighted annualized return; accounts for deposit timing.
Real Return	Return after inflation — change in purchasing power.
Monte Carlo	Running many random simulations to see the range of outcomes.
Probability Cone / Fan	The spread of likely future values from volatility.
Invalidation	The price level that proves an idea wrong — your pre-set exit.

Final reminder. Every number is built from past prices, volume, reported financials, and clearly-labeled assumptions you control. No tool can see tomorrow's news, an earnings surprise, or a devaluation shock. Use this dashboard to organise decisions, size positions, set stops, and track progress toward a real goal — never as the sole reason to act. Start small, always set a stop-loss, and never invest money you cannot afford to lose.
